

Setup: rig assembled on stage, laptop linked, ball ready. 30s combined video queued, muted. Open with the demo, not slides.

[0:00 – COLD OPEN, DEMO FIRST]

Sammy rolls the ball / walks it across the stage; the camera visibly follows.

Don't look at me — look at the tripod. That's a twenty-euro robot cameraman following the ball, live, right now.

[0:20 – THE PROBLEM]

Ninety percent of amateur games are never filmed. Not because nobody wants them — because an auto-tracking camera costs two thousand euros plus a subscription. So kids' games, regional leagues, women's leagues: no footage, no stats, no highlights.

[0:40 – THE PRODUCT]

FollowCam is a retrofit. Two 3D-printed parts — a ring that clamps the tripod you already own, and a fork arm on a metal-gear servo driven by an Arduino. Your phone sits in the head; our app tracks the target on-device and steers the servo. A hundred-degree sweep covers a full court from the scorer's table. Total hardware: about twenty euros.

[1:05 – THE MARKET]

Veo and Pixellot: two thousand plus, locked hardware, priced for clubs that already film. Pivo: consumer gadget that follows one person — and the data dies in the video. We're the third category: cheapest possible capture, and the video is just the input.

[1:25 – THE DATA LAYER]

Sammy: dashboard on screen.

Because the same camera keeps the stats. Today — *today* — our pipeline took real gym footage, tracked every player, read jersey numbers, mapped them onto a 2D court, and computed the score on this dashboard: shots, points, possession timeline, streaming as a live overlay. Points, rebounds, assists is the ladder we're climbing — and heart-rate sync tells a player when their pulse left the zone and their mistakes spiked.

[1:55 – HOW THE DAY ACTUALLY WENT]

Honest build story: our printed servo pocket was sized for the small servo, and the good one didn't fit — the design's zip-tie ledges saved us in five minutes. One jumper wire was dead. The camera preview shipped black once. Every fix is a commit — the whole day is public on GitHub as of an hour ago.

[2:15 – CLOSE]

One servo, two printed parts, the phone in your pocket — and every game finally counts. FollowCam: film the game, keep the stats, twenty euros. Thank you.

Q&A AMMO

"Does it work outdoors / other sports?"

Tracking is class-based — swap the target class. The mount fits any pan-handle tripod. Handball footage is literally what the dashboard ran on today.

"Accuracy of the stats?"

Human-eval harness is in the repo (vision/stats/eval_human.py); shot events carry confirmed flags; the QA page forces re-checks when the system's call changes. We ship measured numbers, not vibes.

"Why will you beat Pivo?"

Pivo sells a gimbal. We sell the game: capture is the cheapest part of the stack, the stats layer is the moat — and our capture is 10x cheaper than theirs anyway.

"What's next?"

Hoop-class fine-tune → automatic made/missed → rebounds → assists; WHOOP-calibrated fatigue analytics; auto-scorekeeping with human veto for volunteer-run leagues.
